# 1. Overview

HG series chemical process pumps are single-stage single-suction cantilever centrifugal pumps. The pump has excellent performance, good anti-cavitation performance, strong load-bearing capacity, long service life of mechanical seals and bearings, reliable operation, novel structure, and is easy maintenance. The pump rotates clockwise when viewed from the drive end.

It is suitable for transporting pure liquid or liquid containing trace amounts of fine particles, and the medium temperature is 80°C-240°C, neutral or corrosive liquid.

**Applications include:**

- ✓ Refineries, petrochemical industry, coal processing industry and cryogenic engineering
- ✓ Chemical industry, paper making, pulp industry, sugar industry and general process industry
- ✓ Water supply plant, sea water desalination plant
- ✓ Heating and air conditioning systems
- ✓ Power plant
- ✓ Environmental pollution protection project
- ✓ Shipbuilding and offshore industry

**Transporting media include:**

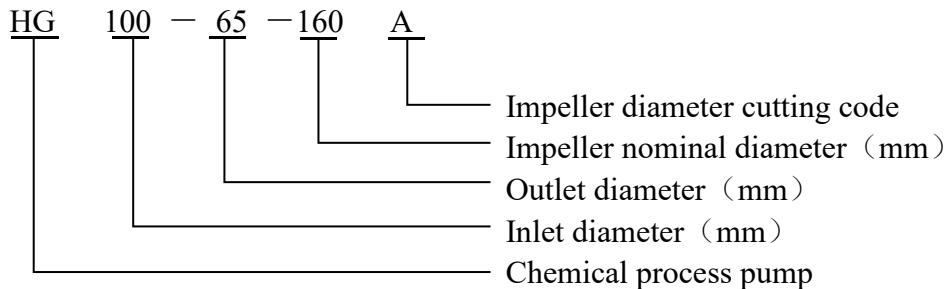

- Inorganic and organic acids
- Liquid petrochemical products, organic compounds, and other corrosive raw materials and products.

**Technical parameter:**

- Flow range: 2—480m<sup>3</sup>/h

● Head range: 3—150m

Model type instruction:

Design feature	Advantage	Economic benefit
Thickened heavy-duty shaft	The deflection of the shaft at the mechanical seal is less than 0.05mm; Long mechanical seal life; Bearing life doubled	Reduce maintenance costs for mechanical seals and bearings Reduce equipment downtime losses due to pump failure
Forced internal cooling cartridge mechanical seal; Spacious shaft seal cavity	Improved mechanical seal cooling and lubrication conditions; Avoid the accumulation of solid particles and gas on the sealing surface; Cartridge type requires no adjustment of axial compression of the mechanical seal	Extend mechanical seal life Reduce pump failures and downtime Install the mechanical seal quickly and reliably
Impeller and shaft are threaded; The impeller inlet is a guide cone; The pump body inlet is equipped with an airfoil cross-section vortex elimination plate	The required NPSH is significantly reduced; Eliminates risk of impeller nut loosening; The seal between the shaft and the impeller is reliable and the shaft is not easily corroded	For harsh cavitation conditions, users do not have to raise settings, saving investment and improving pump reliability.
Simple and fast rotor axial adjustment method	Maintain low pressure in the shaft seal cavity for a long time and reduce axial force	Extended mechanical seal and bearing life
Extra large volume oil pool with water-cooling jacket at the bottom of the pool	The temperature of the lubricating oil decreases, making it suitable for transporting high-temperature media	Extend bearing life Expand the scope of use
The bearing box and the middle connecting seat are integrated into one, the middle seat is spacious	The pump support has high rigidity, which reduces the impact of pipeline load. The mechanical seal and piping	Extend mechanical seal and bearing life Avoid eccentric wear of pump

## Sichuan Zhongying Industrial Pump CO., LTD

and the window is wide	are convenient for maintenance.	body sealing ring
Pump body and pump cover with heating or cooling jacket	Used to transport molten sulfur, polymer or high temperature media	Expand the scope of use of the pump Improve the reliability of pumps for special media
Pump body center support	Suitable for high temperature operation (150—350°C)	
Counter Pressure Packing Seal	The packing pressing force distribution is consistent with the sealing pressure distribution	Excellent sealing effect and long packing life
Secondary impeller power seal	For high solids content and low pump inlet pressures	Lower cost than mechanical seals for slurry
highly interchangeable products	Reduced number of spare parts and shorter lead time	Saving spare parts costs

Parts	Materials		
		Cast steel	Stainless steel
		ASTM	ASTM
1	Casing	grey cast iron	CA-15 CA-15M
2			CF-3(304L) CF-8(304)
3			CF-8M(316) CF-3M(316L)
4			CN-7M(320) CD-4MCu
5	Sealing gasket	asbestos rubber	
6	Shaft	3Cr13	
7	Sealing end cap	CD-4MCu	
8	Shaft sleeve	CD-4MCu	
9	Front end cap	Gray cast iron; Ductile iron; Cast steel	
10	Front bearing	Deep groove ball bearings	
11	Bearing housing	Gray cast iron; Ductile iron; Cast steel	
12	O-ring	Oil resistant rubber	
13	Rear bearing	Double row radial thrust ball bearing	
14	Bearing cover	Gray cast iron; Ductile iron; Cast steel	

15	lock nut and washer	Steel
16	Oil seal	Oil Resistant Rubber

## Structure description

The impeller and the shaft are threaded. When the pump is running or stopped, the medium flows back. The direction of the force acting on the impeller is counterclockwise, tightening the impeller. The impeller uses back blades and an orifice ring to balance the shaft.

The pump cover is positioned with the bearing box through a stop, and the pump cover is fixed and clamped in the middle through the connection between the pump body and the bearing box. The pump body adopts axial suction, radial discharge, foot support type, and can be directly fixed on the base. The side clearance between the impeller back blade and the pump cover can be adjusted by adjusting screws.

For easy disassembly, the structure of the pump is designed in the form of a rear door, so that the impeller, shaft, shaft seal and bearing components can be removed without moving the pump inlet and outlet pipes (that is, the pump body does not move) during maintenance.

The flushing and cooling interfaces of the pump body, pump cover, bearing box and sealing end cover all adopt tapered pipe threads, which increases the reliability of pipeline sealing. The bearings are rolling bearings, oil lubricated, the oil pool has a large volume, and there is a water-cooling clamp at the bottom of the pool. Depending on the working conditions, the pump body and pump cover can be equipped with heating or cooling jackets to improve the reliability of the pump when used with special media.

Shaft seal: cartridge-type mechanism seal and spacious shaft seal cavity.

The large tapered cavity of the shaft seal box places the mechanical seal in a spacious cavity. At the same time, it cooperates with the back blade and the guide vane on the inner wall of the cavity to form a self-flushing flow field in the shaft seal box, thereby eliminating the need for contact. External flushing fluid realizes self-flushing; it also

quickly takes away the heat generated on the friction surface, avoiding the accumulation of solid particles (<5%) in the medium on the contact surface of the rotating ring and the stationary ring, reducing wear and prolonging the mechanical seal life span.

The compensating element (spring) is designed to be isolated from the medium, reducing corrosion resistance requirements and costs, while also extending service life. The addition of a deflector cylinder inside the seal effectively realizes forced circulation inside the seal and further extends the life of the mechanical seal.

## 2. Performance sheet

Sichuan Zhongying Industrial Pump CO., LTD

### **3. Assembly and disassembly**

#### **Pump disassembly sequence**

- (1) Unscrew the drain pipe plug on the pump body and the oil drain pipe plug on the shaft on the box body, drain the liquid in the pump and the oil in the oil pool in the bearing box. If there is an external liquid sealing pipeline, it should also be removed.
- (2) Remove the connecting bolts between the pump body and the bearing box, and take out all the rotor components such as the bearing box components, pump cover, and shaft seal components from the pump body (the motor should be removed before this)
- (3) Unscrew the impeller
- (4) Loosen the set screw between the mechanical seal and the shaft, remove the pump cover together with the cartridge seal assembly from the shaft, then disassemble the mechanical seal end cover and take out the mechanical seal.
- (5) Remove pump coupling and key
- (6) Remove the gland of the bearing at the front end of the bearing box and its skeleton oil seal (if it is a labyrinth seal, remove the dust plate and then take the shaft, bearing and bearing box out of the bearing box).
- (7) Loosen the bearing fixing nut on the bearing box, remove the bearing box and skeleton oil seal, unscrew the hex nut on the shaft, and remove the front and rear bearings and shaft.

#### **Parts inspection**

**Check the wear of parts and repair or replace damaged parts.**

(1) Impeller and rotation clearance.

Check the wear of the impeller and replace it if it is seriously damaged.

Check the clearance between impeller and mouth ring. If the gap exceeds the requirements in Table 3, repair or replace with new parts according to the values in the table.

Diameter at the gap between impeller and mouth ring (mm)	<75	75~140	>140~200	>200~320	>320~400
Clearance value for new part (mm)	Cast iron	0.3	0.4	0.5	0.6
	Steel	0.5	0.6	0.7	0.8
Clearance value for old part (mm)	Cast iron	0.9	1.2	1.5	1.8
	Steel	1.5	1.8	2.0	2.8

Table 3

(2) Mechanical seal components

The friction surfaces of the rotating ring and the stationary ring must be free of any scratches. If there are scratches, they need to be reground and polished or replaced.

(3) Bearing

Clean and inspect bearings and replace if damaged.

### Reassemble

Clean all pump parts. Immerse the bearing in hot oil, heat it to about 800°C, and then install it on the shaft. Other parts are disassembled and assembled into the complete machine in sequence. When assembling, pay attention to check the gaskets on each sealing surface. The seals should be intact and must not be missed.

## 4. Installation

(1) Check the pump and motor after unpacking. If it is confirmed that there is no

damage caused by loading, unloading and transportation, or loose fastening parts, the pump inlet and outlet seals are intact, and no dust, dirt, etc. have entered the pump, then There is no need to re-disassemble and assemble, it can be sent directly to the use site for installation.

- (2) The foundation plane on which the pump is installed should be leveled with a level. After the foundation cement has solidified, place the pump on the foundation and use a level to check the level of the pump and motor shaft. The maximum allowable deviation is 0.1mm/m. If it is not level, use a pad to correct it until level. The base and anchor bolt holes are then poured with cement through the grout holes.
- (3) After the cement is dry, check whether the base and anchor bolt holes are loose. If appropriate, tighten the anchor bolts and recheck the levelness.
- (4) When the motor, pump and base are reinstalled, the concentricity of the pump shaft and motor shaft should be strictly checked. The difference between the upper, lower, left and right outer circles of the measured coupling shall not exceed 0.1mm, and the maximum and minimum gap difference between the end faces of the two couplings in one circle shall not exceed 0.3mm.
- (5) The suction pipeline and pressure pipeline of the pump should have their own brackets. The weight of the pipeline is not allowed to be directly carried by the pump to avoid crushing the pump.
- (6) When the installation position of the pump is higher than the liquid level (within the allowable range of the pump's suction lift), a bottom valve should be installed at the end of the suction pipe, and a filling screw hole or valve should be set on the discharge pipe for filling the pump before starting. Use. When the pump is installed at the liquid level (filling state), a control valve and filter device should be installed on the suction pipeline to prevent debris from being sucked into the pump.

- (7) Irregular pipelines and elbows with small turning radius should be avoided, otherwise the resistance will increase, especially for the suction pipeline of the pump. Large pipeline resistance will cause the pressure at the pump inlet to decrease and affect the performance of the pump. The suction capacity of the pump will seriously cause cavitation and the pump will not work properly.

## 5. Operation

### To start

- (1) Prepare necessary tools.
- (2) Check the oil level in the bearing box oil pool. It should be controlled at a position about 2 mm from the center of the oil mark.

Lubricating oil must not contain any impurities, acid or resin, etc. See (Table 4) for the selection of lubricating oil.

Temperature (°C)		ISO Viscosity grade	kinematic viscosity (mm <sup>2</sup> /s)		minimum ignition point (°C)
Oil chamber	Bearing support		40°C	50°C	
40~65	>50~75	VG46	45	25	145
65~75	>75~85	VG68	65	36	145

Table 4

First, add lubricating oil through the oil filling hole on the bearing box until oil is visible in the branch pipe of the constant oil cup or until it reaches the indicator line on the oil indicator window of the oil storage room.

Add oil to the constant level oil cup as shown in (Picture 4), and then return the oil cup to the working position (Picture 5). If the amount of oil in the oil cup is less than

2/3 of its capacity when the oil cup is in the working position, repeat the above process until there is 2/3 of the oil in the oil cup.

After a period of use, if the oil level in the oil pool of the bearing box drops, repeat the process of 6.1.2.2.2 until the requirements are reached.

- (3) Since the impeller and shaft are threaded, when using it for the first time, disengage the coupling and jog the motor to confirm that the direction is correct before use. Reverse rotation is strictly prohibited.
- (4) When turning the coupling by hand, you should feel the rotation and even weight, and pay attention to identify whether there are any noises such as friction and foreign objects rolling in the pump. If so, try to eliminate it. And install the coupling cover.
- (5) When the installation position of the pump is lower than the liquid level (in the case of filling), before starting, the gate valve of the suction pipe should be opened so that the liquid fills the pump; if the installation position of the pump is higher than the liquid level (in the case of vacuum), the suction pipe must be installed at the bottom. valve. Before starting, open the inlet pipeline valve, fill the pump with transport medium to exhaust or use a vacuum pump to suction.
- (6) Open the valve in the auxiliary equipment line. Close the inlet and outlet pressure (or vacuum) gauge and pressure outlet pipeline gate valve, start the motor, open the inlet and outlet pressure gauge, and then slowly open the outlet pipeline gate valve to the required position.

## **Operation and maintenance**

- (1) During operation, check the smoothness of the pump unit's operation and observe whether there is any vibration. If any abnormal sound or other faults are found, stop the pump immediately for inspection and continue operation only after the fault is eliminated.
- (2) Always check the temperature rise of the pump and motor. The temperature rise of the bearings should not be higher than 350°C, and the limit temperature should not be greater than 750°C.
- (3) Pay attention to changes in the oil level in the oil storage chamber of the bearing box, and always control it within the specified range. When used for the first time or reused after bearing maintenance, the oil should be drained after the pump has been running for 10 to 15 hours, clean the oil storage chamber, inject new lubricating oil, and then put it into normal operation. During normal use, press (Table 5) requires regular replacement of lubricating oil.

Temperature (°C)		Replacement cycle (month)
Oil chamber	Bearing support	
40~65	>50~75	12
65~75	>75~80	6

Table 5

- (4) Never use the gate valve in the suction line to adjust the flow to avoid cavitation.
- (5) The pump is generally not suitable for long-term operation at less than 30% of the design flow rate. If it must be used under such conditions, a bypass pipe should be installed on the outlet pipeline to ensure that the pump flow rate reaches the specified use range.
- (6) Check auxiliary systems frequently during use
- (7) In the case of a spare pump, in order to ensure that the pump can be put into use immediately, trial runs should be carried out regularly.

#### **to stop**

- (1) Slowly close the pressure outlet line gate valve.
- (2) Turn off the motor and observe the rotor continuously and slowly stopping and

advancing.

- (3) Close the inlet and outlet pressure (vacuum) gauges, and in the case of filling, close the suction pipeline gate valve. If external liquid drainage is used for sealing, the external liquid drainage valve must also be closed.
- (4) If the ambient temperature is lower than the freezing point of the liquid, the liquid in the pump must be drained to prevent freezing and cracking.
- (5) For pumps that have been out of use for a long time, in addition to draining the corrosive liquid in the pump, they must also be rinsed with clean water, especially the sealing chamber, which must be carefully rinsed. It is best to disassemble the pump, clean it and reinstall it, and seal the inlet and outlet of the pump and keep it in a safe place.

## 6. Precautions when using mechanical seals

This series of pumps adopt cartridge seals. Different forms of mechanical seals can also be installed according to different usage conditions or user needs, such as internal single balanced type and unbalanced type, double balanced type and unbalanced type, and external mechanical seal, etc. Therefore, depending on the type of seal selected, its usage and precautions are also different. Here are some things to note:

- (1) The cartridge mechanical seal consists of a retainer, a rotating ring, a stationary ring, a spring, a gland, and an end cover arranged outside the shaft sleeve in order, and is integrated with the shaft sleeve through a pallet, a snap ring, and a set screw. After the cartridge mechanical seal and pump are assembled, use set screws for axial positioning. Before pumping, be sure to remove the pallet and keep it. When it is necessary to adjust the axial clearance between the impeller back blade and the pump cover (adjusted through the bolts on the bearing box), just loosen the set screw.
- (2) The mechanical seal should be disassembled carefully, and it is not allowed to use hand hammers, iron tools, etc. to knock, so as not to damage the dynamic and

static sealing surfaces.

- (3) Before installing the mechanical seal, check whether any sealing components are invalid or damaged. If any, they should be repaired or replaced with new ones.
- (4) The grinding sealing end faces of the rotating ring and the stationary ring should be strictly inspected, and no minor scratches, bruises or other defects are allowed. All mechanical seal parts, including pump body, impeller, seal chamber, etc., should be rinsed before assembly. Especially the rotating ring and static ring end face should be carefully wiped clean with a clean, soft cloth or cotton gauze, and then coated with a layer of cleaning grease or engine oil.
- (5) During assembly, attention should be paid to eliminating deviations. When tightening the screws, press them evenly to avoid deflection and seal failure.
- (6) The cartridge mechanical seal does not need to adjust the hydraulic pressure of the spring (the manufacturer has already adjusted it). For mechanical seals that need to adjust the spring compression, they must be adjusted correctly so that the spring is not too tight or too loose. After the pump is installed, when you turn the rotor by hand, you should feel that the electric seal spring has a certain amount of compression, and it can rotate easily and flexibly without any feeling of bite. If there is any abnormality, it must be checked and adjusted.
- (7) For mechanical seals with external flushing, the flushing fluid should be opened to fill the sealing cavity with sealing fluid before overspending. When stopping, stop the pump first and close the seal flushing fluid.

## 7. Troubleshooting

Table 6

Problem	Cause	Solution
Bearing overheating	<ul style="list-style-type: none"> <li>1. Too much or too little lubricant</li> <li>2. Lubricating oil deteriorates</li> <li>3. The crew is not aligned</li> <li>4. Vibration</li> </ul>	<ul style="list-style-type: none"> <li>1. Reduce fuel or add fuel</li> <li>2. Drain and clean the oil pool and add new oil</li> <li>3. Readjust concentricity</li> <li>4. Check the balance of the rotor or operate it at a smaller flow rate</li> </ul>
Pump cannot pump liquid	<ul style="list-style-type: none"> <li>1. There is air left in the suction pipe or inside the pump</li> <li>2. Pipe valve is closed on the inlet or outlet side</li> <li>3. Operation head is higher than the maximum head of the pump.</li> <li>4. Air leakage in pump suction pipe</li> <li>5. The impeller direction of rotation is incorrect</li> <li>6. The suction height is too high</li> <li>7. The suction pipe is too small or blocked by debris</li> <li>8. The speed does not match</li> </ul>	<ul style="list-style-type: none"> <li>1. Fill with liquid; remove air</li> <li>2. Open the valve</li> <li>3. Replace the pump with higher head</li> <li>4. Eliminate leakage on the import side</li> <li>5. Correct the rotation direction of the motor</li> <li>6. Lower the installation height of the pump</li> <li>7. Increase the diameter of the suction pipe and clear the blockage</li> <li>8. Make the motor speed meet the requirements</li> </ul>

Insufficient flow and head	<ol style="list-style-type: none"> <li>1. Damaged impeller</li> <li>2. Excessive wear of the sealing ring</li> <li>3. Insufficient speed</li> <li>4. The inlet or outlet valve is not fully opened</li> <li>5. Air leaks into the suction pipe</li> <li>6. There is a blockage in the pipe</li> <li>7. The medium density does not match the pump requirements.</li> <li>8. The device head does not match the pump head.</li> </ol>	<ol style="list-style-type: none"> <li>1. Replace with new impeller</li> <li>2. Replace the sealing ring</li> <li>3. Increase the speed as required</li> <li>4. Fully open</li> <li>5. Seal the leakage well</li> <li>6. Eliminate blockages</li> <li>7. Recalculate or replace the motor with appropriate power</li> <li>8. Try to lower the installation height of the pump</li> </ol>
Severe seal leakage	<ol style="list-style-type: none"> <li>1. Improper selection of sealing component materials</li> <li>2. The friction pair is severely worn</li> <li>3. The rotating and stationary rings are unevenly matched</li> <li>4. The friction pair is too large and the stationary ring is broken.</li> <li>5. O-ring damaged</li> </ol>	<ol style="list-style-type: none"> <li>1. Explain the medium conditions to the manufacturer to provide appropriate seals</li> <li>2. Replace worn parts and adjust spring pressure</li> <li>3. Readjust the sealing assembly</li> <li>4. Replace the stationary ring so that the verticality error with the shaft is less than 0.10, and install the seal assembly as required.</li> <li>5. Replace the O-ring</li> </ol>

Pump vibrates and makes noise	<ol style="list-style-type: none"> <li>1. The center lines of the pump shaft and the motor shaft are not aligned</li> <li>2. Shaft bending</li> <li>3. Bearing wear</li> <li>4. Cavitation occurs in the pump</li> <li>5. Friction between rotating parts and fixed parts</li> <li>6. Rotating parts lose balance</li> <li>7. There is debris blocking the pipeline or pump.</li> <li>8. The inlet valve is not fastened</li> </ol>	<ol style="list-style-type: none"> <li>1. Adjust to alignment</li> <li>2. Replace with new oil</li> <li>3. Replace bearings</li> <li>4. Consult the manufacturer</li> <li>5. Repair the pump or improve its usage</li> <li>6. Check the cause and try to eliminate it</li> <li>7. Check the sewage discharge</li> <li>8. Open the inlet valve and adjust the outlet valve</li> </ol>
Motor overload	<ol style="list-style-type: none"> <li>1. The pump and motor are not aligned</li> <li>2. The relative density of the medium becomes larger</li> <li>3. Friction occurs in rotating parts</li> <li>4. The device resistance becomes lower, making the operating point tend to be at a higher flow rate.</li> </ol>	<ol style="list-style-type: none"> <li>1. Adjust the alignment</li> <li>2. Change the operating process</li> <li>3. Repair friction parts</li> <li>4. Check the pressure of the suction and discharge pipelines and adjust them accordingly.</li> </ol>

## 8. Pump sets of supply range

- (1) pump: 1;
- (2) motor: 1;
- (3) base and coupling guard: 1 each
- (4) spare parts: impellers, sealing rings, etc. are supplied according to contract.
